Viele — MVP Build Plan

For review and confirmation

Status	Draft for Eugene's confirmation
Date	2026-06-08
From	Akash
Purpose	Confirm the features and functionality of the first build (MVP) before we finalize and start building
Companion docs	<code>PRD.docx</code> (original), <code>docs/SRS.md</code> (full long-term vision)

This document is the **MVP slice**. The full product vision (all five tabs, posting, Catwalk, etc.) still lives in the SRS and is not cancelled. We are simply building the core first and adding the rest in phases.

1. What we're building, in one sentence

Open the app and within about a minute, see real outfits worn by people built like you, in your style, and save the ones you love. Open to everyone, every body type and gender, from day one.

That single moment, "these are outfits on people who actually look like me," is the whole bet of the MVP.

2. Why this exact scope

We looked at the market and at why apps like this fail. Two patterns kill them:

1. **Too much onboarding before any value.** Asking for a body scan + face scan + lots of taps before showing a single outfit causes heavy drop-off (camera-first onboarding can lose 25-60% of users). **Our fix:** the scan stays, but it comes *after* the user sees value, as an upgrade, not a gate.

2. **No content on day one.** A “people like you” feed is empty without a large, body-diverse library. **Our fix:** see Section 6.

Competitors exist (Mys-Tyler, Glance AI), so we are not first to “inclusive fashion inspiration.” We win on **body-accurate matching**, which is exactly where the body-scan engine is our advantage.

3. The core experience (MVP user flow)

1. Open app
| (no account, no camera yet)
▼
 2. Pick 3+ aesthetics + pick body type from an illustrated selector
| (or quick height/weight)
▼
 3. SEE THE FEED ← the wow
| outfits on people with a similar body, in your aesthetics
▼
 4. Tap an outfit → see the tagged clothing items
|
▼
 5. Save one you love → here we ask you to create an account
| (Google / Apple / email)
▼
 6. "Want this tuned to your exact proportions? 10-second scan."
optional body scan (sharpens the matching). Never required.
-

4. Features IN the MVP

Feature	What it does
Lightweight onboarding	Pick aesthetics + body type from illustrated options. No camera and no account needed to start.
Personalized similar-body feed	The home experience. Ranks outfits by body similarity + aesthetic match. This is the product.
Outfit detail	Tap any outfit to see the clothing items tagged in it.
Save + collection	Save outfits to a collection. Account creation is prompted at the first save.
Account & auth	Google, Apple, and email sign-in (via Supabase).
Optional body scan	The body-scan engine, offered after the first wow as an accuracy upgrade. Results are editable. Runs on-device.
Body-tagged content library	Outfit content sourced from creators and auto-tagged for body type (see Section 5 and 6).
Open to everyone	Any body type, gender, or aesthetic can install and get a useful feed on day one.
Privacy by design	Scan video and any photos are processed on the device and never uploaded. Only the derived profile and matching vector are stored.

5. How the matching works (the moat)

This is the heart of Viele, and the part that needs Eugene's confirmation.

The key idea: the same body/pose technology we use to scan *users* also runs on *content images* to estimate the body type of the person wearing each outfit. That lets us **auto-tag the whole catalog by body type** without manual work, which is what makes “open to everyone” actually work.

- Every **user** gets a body vector (rough from the body-type pick, precise after the scan).
 - Every **content item** gets a body vector (estimated by the pose pipeline) plus aesthetic and attribute tags.
 - The feed matches user vector to content vectors and ranks by body similarity and aesthetic. Where a user sits in a thin part of the catalog, we relax the body tolerance and lean on aesthetic so the feed is never empty, then improve precision as the catalog grows.
-

6. Content & cold-start plan

A body-matched feed needs a large, body-diverse library on day one. Brand catalogs are easy to license but mostly show model bodies, which is the opposite of the diversity we need. Real diversity comes from real people. So:

- **Recruit a body-diverse creator roster** to seed authentic outfit content across body types.
 - **Auto-body-tag everything** with the pose pipeline (Section 5).
 - **Graceful degradation** keeps every feed populated while the catalog fills.
 - **No user posting (UGC) in the MVP**, which also means almost no content-moderation burden at launch.
-

7. Technology

Layer	Choice
Mobile app	Flutter (iOS + Android)
Backend	Supabase: Auth, Postgres with Row Level Security, Storage, and pgvector for the matching vectors. Provisioned as a brand-new, fully isolated project (nothing shared with any other Supabase project).
Body scan	Dart port of the existing body-scan engine, preserving the measurement algorithm. Capture layer rebuilt natively.
Content tagging	The same pose pipeline, run on content images.
Admin	A thin internal content-seeding tool (React) at MVP. Full admin dashboard is deferred.
Privacy	On-device processing of all body/face imagery; raw imagery is never uploaded.

8. Explicitly NOT in the MVP (deferred, not cancelled)

Deferred	Why it can wait
Discover swipe deck	The feed proves the core loop first; swipe is an engagement add-on.
User posting / Create (UGC)	Content is creator-seeded at MVP; this also removes moderation work.
Catwalk, leaderboards, trending	Needs scale and content that doesn't exist yet.
Complexion / coloring detection	A second camera step we don't need to prove the core wow.
Following / creators / full social graph	Beyond the core save loop.
Full admin dashboard	No public posting means minimal moderation at MVP.
Advanced recommendations ("why recommended", collaborative filtering, exploration)	MVP is body + aesthetic matching. Earn the complexity with real data.
Brands, budget range, fashion goals capture	Not needed for the first wow.

All of these remain in `docs/SRS.md` as later phases.

9. Open questions for Eugene (please confirm)

1. **Auto-tagging content [most important]:** can the pose/body pipeline run on third-party *content images* (not just live user capture) to estimate the wearer's body type? What accuracy can we expect from a single photo vs. the multi-frame user scan?
2. **Repo access:** can we get the existing TypeScript body-scan implementation as the reference for the Dart port?
3. **Scan input on Flutter:** keep the ~10-second video, or move to photos for the mobile capture?
4. **Rough match before scan:** is body matching from the illustrated body-type pick (a coarse body vector) good enough to make the first feed feel relevant before the user scans?
5. **Vector format:** any constraints from the engine on the body-vector shape/normalization we should standardize for pgvector similarity?

6. **Complexion detection:** confirm it stays out of the MVP (deferred to a later phase).

10. Not being decided yet

- Monetization / business model (shopping links, creator monetization) is a later-phase question.
 - Exact creator-program terms (who, how paid, rights) to be defined as we line up the roster.
-

Once Eugene confirms Sections 5, 6, and 9, we finalize this as the MVP scope and reconcile `docs/SRS.md` to mark MVP vs. later phases.
